**Macular Evaluation in Vogt-Koyanagi-Harada's Syndrome (VKH) by Optical Coherence Tomography (OCT)**

R. Andrade, C. Muccioli, M.E. Farah, R. Belfort Jr. Purpose: To evaluate macular abnormalities in VKH by OCT. Methods: Thirty patients (90% female) had their macular anatomic status evaluated by OCT. Results: OCT findings comprised focal atrophic areas (30%), serous retinal detachment (36,6%), choroidal neovascularization (5,0%), subretinal fibrosis (6,6%), cystoid macular edema (3,3%), as well as choroidal and retinal fluid images. Conclusion: OCT was useful to demonstrate additional morphological findings and persistent macular alterations in spite of a favorable visual acuity outcome. Thus cross-sectional OCT images may increase understanding of the pathophysiology of VKH.
